

Evolution's Erratic Pace

by Stephen Jay Gould

"Natural History," May, 1977

Pgs 14 and 16

*The history of life contains
"long periods of boredom
and short periods of terror"*

On November 23, 1859, the day before his revolutionary book hit the stands, Charles Darwin received an extraordinary letter from his friend Thomas Henry Huxley. It offered warm support in the coming conflict, even the supreme sacrifice: "I am prepared to go to the stake, if requisite ... I am sharpening up my claws and beak in readiness." But it also contained a warning: -You have loaded yourself with an unnecessary difficulty in adopting *Natura non facit saltum* so unreservedly." The Latin phrase, usually attributed to Linnaeus, states that -nature does not make leaps." Darwin was a strict adherent to this ancient motto. As a disciple of Charles Lyell, the apostle of gradualism in geology. Darwin portrayed evolution as a stately and orderly process working at a speed so slow that no person could hope to observe it in a lifetime. Ancestors and descendants, Darwin argued, must be connected by "infinitely numerous transitional links "forming "the finest graduated steps." Only an immense span of time had permitted such a sluggish process to achieve so much.

Huxley felt that Darwin was digging a ditch for his own theory. Natural selection required no postulate about rates; it could operate just as well if evolution proceeded at a rapid pace. The -road ahead was rocky enough-, why harness the theory of natural selection to an assumption both unnecessary and probably false'? The fossil record offered no support for gradual change: whole faunas had been wiped out during disarmingly short intervals (see my column of October 1974). New species almost-always appeared suddenly in the fossil record with no intermediate links to ancestors in older rocks of the same region. Evolution, Huxley believed, could proceed so rapidly that the slow and imperfect process of sedimentation rarely caught it in the act.

The conflict between adherents of rapid and those of gradual change had been particularly intense in geologic circles during the years of Darwin's apprenticeship in science. I do not know why Darwin chose to follow Lyell and the gradualists so strictly, but I am certain of one thing: preference for one view or the other had nothing to do with superior perception of empirical information. On this question, nature spoke (and continues to speak) ambiguously anti multifariously. Cultural and methodological preferences *had as much influence upon any decision as the actual data.

On issues so fundamental as a -general philosophy of change, science and society usually work hand in hand. The static systems of European monarchies won support from legions of scholars as the embodiment of natural law. Alexander Pope wrote:

Order is Heaven's first law;
and this confessed.
Some are, and must be,
greater than the rest.

As monarchies fell and as the late eighteenth century became embroiled in an age of revolution, scientists began to see change as a normal part of universal order, not as aberrant and exceptional. Scholars then transferred to nature the liberal program of slow and orderly change that they advocated for social transformation in human society. Karl Marx recognized the primary path of influence when he wrote to Engels in 1862:

It is remarkable how Darwin recognizes among beasts and plants his English society with its division of labor, competition, opening up of new market. "invention" and Malthusian "struggle for existence."

To many scientists, natural cataclysm seemed as threatening as the reign of terror that had taken their great colleague Lavoisier.

Yet the geologic record seemed to provide as much evidence for cataclysmic as for gradual change. There-fore, in defending gradualism as a nearly universal tempo, Darwin had to use Lyell's most characteristic method of argument-he had to reject literal appearance and common sense for an underlying "reality." (Contrary to popular myths, Darwin and Lyell were not the heroes of true science. defending objectivity against the theological fantasies of such "catastrophists" as Cuvier and Buckland. Catastrophists were as committed to science as any gradualist: in fact, they adopted the more "objective" view that one should believe what one sees and not interpolate missing bits of a gradual record into a literal tale of rapid change.) In short, Darwin argued that the geologic record was exceedingly imperfect -- a book with few remaining pages, few lines on each page, and few words on each line. We do not see slow evolutionary change in the fossil record because we study only one step in thousands. Change seems to be abrupt because the intermediate steps are missing,

The extreme rarity of transitional forms in the fossil record persists as the trade secret of paleontology. The evolutionary trees that adorn our text-books have data only at the tips and nodes of their branches; the rest is inference, however reasonable, not the evidence of fossils. Yet Darwin was so wedded to gradualism that he wagered his entire theory on a denial of this literal record:

The geological record is extremely imperfect and this fact will to a large extent explain why we do not find interminable varieties, connecting together all the extinct and existing forms of life by the finest graduated steps, He who rejects these views on the nature of the geological record, will rightly reject my whole theory.

Darwin's argument still persists as the favored escape of most paleontologists from the embarrassment of a record that seems to show so little of evolution. In exposing its

cultural and methodological roots, I wish in no way to impugn the potential validity of gradualism (for all general views have similar roots). I wish only to point out that it was never -seen- in the rocks.

Paleontologists have paid an exorbitant price for Darwin's argument. We fancy ourselves as the only true students of life's history, yet to preserve our favored account of evolution by natural selection we view our data as so bad that we never see the very process we profess to study.

For several years, Niles Eldredge of the American Museum of Natural History and I have been advocating a resolution of this uncomfortable paradox. We believe that Huxley was right in his warning. The modern theory of evolution --little more than a contemporary restatement of basic Darwinism -- does not require gradual change. In fact, the operation of Darwinian processes should yield exactly what we see in the fossil record.

The history of most fossil species includes two features particularly inconsistent with gradualism:

1. *Stasis*. Most species exhibit no directional change during their tenure on earth. They appear in the fossil record looking much the same as when they disappear; morphological change is usually limited and directionless.

2. *Sudden appearance*. In any local area, a species does not arise gradually by the steady transformation of its ancestors. It appears all at once and "fully formed,"

Evolution proceeds in two major modes. In the first, phyletic transformation, an entire population changes from one state to another. If all evolutionary change occurred in this mode, life would not persist for long. Phyletic evolution yields no increase in diversity, only a transformation of one thing into another. Since extinction (by extirpation, not by evolution into something else) is so common, a biota with no mechanism for increasing diversity would soon be wiped out. The second mode, speciation, replenishes the earth. New species branch off from the persisting parental stock.

Darwin, to be sure, acknowledged and discussed the process of speciation. But he cast his discussion of evolutionary change almost totally in the mold of phyletic transformation. In this context, the phenomena of stasis and sudden appearance could hardly be attributed to anything but imperfection of the record; for if new species arise by the transformation of entire ancestral populations, and if we never see the transformation (because species are essentially static through their range) then our record must be hopelessly incomplete.

Eldredge and I believe that speciation is responsible for almost all evolutionary change. Moreover, the way in which it occurs virtually guarantees that sudden appearance and stasis shall dominate the fossil record.

All major theories of speciation maintain that splitting takes place rapidly in very small populations. The theory of geographic or allopathic, speciation is preferred by most evolutionists for most situations (allopathic means "in another place"). A new species can arise when a small segment of the ancestral population is isolated at the periphery of the ancestral range. Large stable central populations exert a strong, homogenizing influence. New and favorable mutations are diluted by the sheer bulk of the population through which they must spread. They may build slowly in frequency, but changing environments usually alter their value before they reach fixation. Thus, phyletic transformation in large populations should be very rare -- as the fossil record proclaims.

But a species on the periphery is isolated, even cut off from its parental stock. It lives as a tiny population in a geographic corner of the ancestral range. Selective pressures are usually intense because peripheries mark the edge of ecological tolerance for ancestral forms, Favorable variations spread quickly. Small, peripheral isolates are the laboratory of evolution.

What should the fossil record include if most evolution involves the speciation of peripheral isolates? Species should be static through their range because our fossils are the products of large central populations. In any local area inhabited by ancestors, a descendant species should appear suddenly by migration from the peripheral region in which it evolved. In the peripheral region itself, we might find direct evidence of speciation, but such good fortune would be rare indeed because the event occurs so rapidly in such a small population. Thus, the fossil record is a faithful rendering of what evolutionary theory predicts, not a pitiful vestige of a once bountiful tale.

Eldredge and I refer to this scheme as the model of punctuated equilibria. Lineages change little during most of their history, but events of rapid speciation occasionally punctuate this tranquility. Evolution is the differential survival and deployment of these punctuations. Our model is fully consistent with Darwin's central postulate that natural selection controls evolutionary change. Natural selection requires continuity and intermediacy, for selection must create the fit by steadily increasing the frequency of favorable variants. It does not require exceedingly slow and gradual transformation of entire populations. (in describing the speciation of peripheral isolates as very rapid. I speak as a geologist_ The process may take hundreds, even thousands of years, you might see nothing if you stared at bees on a tree for your entire lifetime. But a thousand years is only an instant in the three-billion-year recorded history of life. Geologic resolution is usually far more coarse.)

If gradualism is more a product of Western thought than a fact of nature, then we should consider alternative philosophies of change to enlarge our realm of constraining prejudices. In the Soviet Union, for example, scientists are trained with a very different philosophy of change the so-called dialectical laws, reformulated by Engels from Hegel's philosophy- The dialectical laws are explicitly punctuational. They speak, for example, of the "transformation of quantity into quality." This may sound like mumbo jumbo, but it suggests that change occurs in large leaps following a slow accumulation of stresses that a system resists until it reaches the breaking point. Heat water and it

eventually reaches a boiling point. Oppress the workers more and more and they suddenly break their chains. Eldredge and I were fascinated to learn that most Russian paleontologists support a model very similar to our punctuated equilibria. The connection cannot be accidental.

I emphatically do not assert the general -truth- of this philosophy of punctuational change. Any attempt to support the exclusive validity of such a grandiose notion would border on the nonsensical. Gradualism some- times works well, (I flew over the folded Appalachians this morning and saw the striking parallel ridges left standing by gradual erosion of the softer rocks surrounding them.) I make a simple plea for pluralism in guiding philosophies, and for the recognition that such philosophies, however hidden and unarticulated constrain all our thought. The dialectical laws express an ideology quite openly-, our Western preference for gradualism does the same thing more

Nonetheless I will confess to a personal belief that a punctuational view may prove to map tempos of biological and geologic change more accurately and more often than any of its compositors--if only because complex systems in steady state are both common and highly resistant to change. As my colleague British geologist Derek V. Ager writes in supporting a punctuational view of geologic change: "The history of any one part of the earth, like the life of a soldier consists of long periods of boredom and short periods of terror.
